

How To Plant A Mango Seed

How To Plant A Mango Seed

Downloaded from www2.lacavedespapilles.com by Lexi & Braylon

FROM PIT TO PARADISE: YOUR COMPLETE GUIDE ON HOW TO PLANT A MANGO SEED

There is something deeply satisfying about growing a tree from a single seed. It is a small act of faith, a gamble with nature that, when successful, rewards you with a living, growing monument to your patience. Few experiences in gardening are as rewarding as nurturing a mango tree from the rough, fibrous pit of a fruit you enjoyed on a sunny afternoon. While buying a grafted sapling from a nursery guarantees fruit quality and faster harvests, growing a mango from seed is a project of pure wonder. It is an affordable, accessible, and fascinating journey that connects you to the very origins of the plant. Whether you dream of a backyard tropical oasis or simply want a beautiful, lush houseplant, learning how to plant a mango seed is your first step. This guide will walk you through every stage, from selecting the perfect fruit to caring for your young tree, ensuring you have the best possible chance of success.

SELECTING THE PERFECT MANGO FOR YOUR PROJECT

Before you even think about soil or water, you must start with the right fruit. The success of your entire project hinges on the quality of the seed you begin with. Not every mango from the grocery store is a viable candidate.

Polyembryonic vs. Monoembryonic: The Key Distinction

This is the most important concept in mango seed growing. Mango varieties fall into two categories:

- **Polyembryonic Seeds:** These seeds contain multiple embryos. One is sexual (a cross of the parent trees), while the others are clones of the mother tree. A tree grown from a polyembryonic seed is much more likely to produce fruit similar to the one you ate. Popular polyembryonic varieties include ‘Carrie,’ ‘Dwarf Hawaiian,’ ‘Manila,’ and ‘Strawberry.’ These are the best bets for a seedling that will bear true-to-type fruit.
- **Monoembryonic Seeds:** These seeds contain a single sexual embryo. The resulting tree is a unique hybrid, and its fruit will likely be completely different from (and often inferior to) the parent fruit. Common monoembryonic varieties include the classic ‘Haden,’ ‘Tommy Atkins,’

and ‘Kent.’ While these can still be grown as ornamental trees, their fruit quality is unpredictable.

If your goal is eventually fruit that resembles the mango you bought, try to source a polyembryonic variety. If you simply want a beautiful tree for its foliage and the thrill of growing it, any fresh, healthy mango will do.

What to Look For at the Store

Regardless of the variety, choose a fruit that is fully ripe. The flesh should be soft and give slightly to gentle pressure. The skin will often have a sweet, floral aroma near the stem. Avoid fruits that are overly mushy, have dark sunken spots, or show signs of mold. The best seed comes from the best fruit.

EXTRACTING AND PREPARING THE SEED

Now that you have your perfect mango, it is time to liberate the treasure inside. This step requires care to avoid damaging the seed.

1. **Eat or Cut Away the Fruit:** Enjoy the delicious mango! Cut the fruit off the pit in large slabs. Try to leave as little flesh on the husk as possible. Scrape off any remaining fruit with a spoon or knife.
2. **Clean the Husk:** Rinse the rough, fibrous husk under cool running water. Remove any stray fibers. It should feel clean and damp.
3. **Dry the Seed:** Place the husk on a paper towel in a cool, dry, shaded spot for about 24 to 48 hours. This allows any surface moisture to evaporate. Do not let it sit in direct sunlight, as this can kill the embryo inside. You will notice the husk begin to dry out and harden slightly.
4. **Open the Husk (The Critical Step):** This is where many beginners get nervous. The hard husk is just a protective shell. Inside is the actual seed kernel. Use a pair of heavy-duty scissors, a sharp knife, or a sturdy pair of pruning shears to carefully pry the husk open along its thin, slightly curved edge (the ridge). Work slowly. You want to crack it open without stabbing into the kernel inside. The kernel will look like a large, pale, lima bean. It is slightly rubbery and will be a pale white or light yellow color. Discard the husk.

Important: If you are not ready to plant immediately after extracting the kernel, you can wrap it in a damp paper towel and store it in a sealed plastic bag in the refrigerator for a day or two. Do not let it dry out.

TWO PROVEN METHODS FOR GERMINATING YOUR MANGO SEED

You now have a living kernel. It is time to coax it into life. There are two highly effective methods for germinating a mango seed. Choose the one that best suits your environment and patience level.

Method 1: The Paper Towel Method (Best for Observing Growth)

This method allows you to watch the root and shoot develop, which is incredibly satisfying. It also creates a semi-controlled, humid environment that encourages rapid germination.

1. **Prepare the Paper Towel:** Take a standard paper towel and fold it in half, then in half again. Dampen it thoroughly with room-temperature water. It should be wet but not dripping. Wring out any excess water. You want it moist, not soaking.
2. **Place the Seed:** Lay the damp paper towel flat. Place the mango kernel in the center of the towel. The slight hump or convex side is often the top, but it is not critical. Just lay it flat.
3. **Create a Humid Chamber:** Fold the paper towel over the kernel so it is completely enclosed. Place this wrapped seed inside a clear, sealable plastic bag (like a ziplock bag). Press out as much air as possible before sealing. This creates a miniature greenhouse.
4. **Find the Right Spot:** Place the bag in a warm, dark location. The top of a refrigerator, a high kitchen cabinet, or an area with consistent room temperature (70-85°F / 21-29°C) is perfect. Avoid direct sunlight, as this can overheat the bag and cook the seed.
5. **Check and Wait:** Check the bag every 2-3 days. You will likely see condensation inside, which is perfect. After 1 to 3 weeks, you should see a small, pinkish root emerge from one end of the kernel. A short green shoot will follow shortly.
6. **Pot It Up:** Once the root is about an inch long, it is time to plant the germinated seed in soil. Handle it carefully.

Method 2: Direct Soil Planting (The "Set and Forget" Method)

This method mimics what happens in nature. It is simpler and less prone to transplant shock, but it requires patience, as you will not see the early growth.

1. **Prepare the Pot and Soil:** Choose a pot that is at least 6-8 inches deep with drainage holes. Fill it with a high-quality, well-draining potting mix. A mix designed for palms or citrus is excellent. You can also mix standard potting soil with perlite or coarse sand to improve drainage.
2. **Plant the Seed:** Make a hole in the center of the soil about 1-2 inches deep. Place the mango

kernel into the hole, flat side down, with the convex side facing up. The small "eye" or point where the root will emerge should be slightly angled downward.

3. **Cover and Water:** Gently cover the seed with soil. Water it thoroughly until water runs out of the drainage holes. The soil should be evenly moist but not waterlogged.
4. **Create a Mini Greenhouse:** To retain warmth and humidity, cover the pot with a clear plastic bag or a plastic dome. This creates a humid environment that mimics the tropics. Remove the cover for 30 minutes each day to allow air circulation.
5. **Provide Warmth and Light:** Place the pot in a warm location with bright, indirect light. A warm windowsill works well. Avoid direct, scorching sun on the plastic cover, as it can overheat.
6. **Wait Patiently:** Keep the soil consistently moist. A seedling may emerge in 2-4 weeks. Once you see a small green shoot breaking the surface, you can remove the plastic cover permanently.

CARING FOR YOUR YOUNG MANGO SEEDLING

Congratulations! You have a tiny mango tree. The first few months are crucial for establishing a strong foundation.

Light and Location

Mangoes are sun-worshippers. Once your seedling is established (has 4-6 true leaves), give it as much direct sunlight as possible. A south-facing window is ideal in the Northern Hemisphere. If you lack natural light, a full-spectrum grow light placed just a few inches above the plant for 12-14 hours a day will work wonders. Insufficient light will result in a "leggy" tree with thin, weak stems and pale leaves.

Watering: The Goldilocks Principle

Mango seedlings like consistent moisture, but they hate soggy feet. The key is to water deeply when the top inch of soil feels dry to the touch. Stick your finger into the soil. If it is dry, water thoroughly until water drains out. If it is still moist, wait a day or two. Overwatering is the single most common cause of seedling death, leading to root rot. Underwatering will cause the leaves to wilt and drop. Find the happy medium.

Potting Up: Giving Roots Room to Grow

Your seedling will quickly outgrow its small starter pot. When you see roots emerging from the drainage holes, or when the plant is noticeably top-heavy, it is time to repot. Move it to a pot that is 2-3 inches larger in diameter. **Do not** jump to a giant pot, as the excess soil can hold too much moisture and cause root rot. Use a well-draining potting mix. Aim for a pot that is at least 15-20

gallons if you plan to keep it as a container tree for several years.

Fertilizing for Growth

Mangoes are moderate feeders. Begin fertilizing your seedling about 2-3 months after it germinates. Use a balanced, slow-release fertilizer with a ratio like 6-6-6 or 8-3-9. **Follow the package instructions carefully.** Over-fertilizing, especially with nitrogen, can burn the roots and kill the plant. Fertilize lightly every 4-6 weeks during the growing season (spring and summer) and stop in the fall and winter.

OVERCOMING COMMON CHALLENGES

Even with the best care, you may encounter some bumps in the road. Here is how to address them.

- **Seed Rot (Mushy, Smelly Seed):** This is almost always caused by overwatering. Ensure your pot has drainage holes, and you are not keeping the soil waterlogged. If the seed has

rotted, it cannot be saved. You must start again with a new seed.

- **Leggy Seedling (Tall, Thin, Weak Stem):** This signals a lack of light. Move the plant immediately to a sunnier spot or invest in a grow light. You can slightly bury the lower part of the stem when repotting to encourage stronger root growth.
- **Pests (Aphids, Spider Mites, Mealybugs):** Young mango trees can be attacked by common houseplant pests. Inspect the leaves regularly. A strong blast of water from a spray bottle can dislodge aphids. For more persistent infestations, use insecticidal soap or neem oil, following the label directions.
- **Leaf Burn (Brown, Crispy Edges):** This can be caused by too much direct sun (if the seedling was not acclimated), over-fertilization, or salt buildup from tap water. Use filtered or distilled water, or let tap water sit out overnight. Flush the soil thoroughly every few months to remove excess salts.
- **Why Is My Tree Not Fruiting?** This is the biggest disappointment for many. A mango tree grown from a monoembryonic seed may never fruit, or its fruit may be small and stringy. Even a polyembryonic tree can take 5 to 10 years or more to flower.
